

# Overflows & Format Strings

### Announcements...

#### Computer Science 161 Fall 202

Moovo

- Reminder: CS61C (Call Frame) review session tomorrow 12:30-2
- Project 1 and Homework 1 are both out
- Zoom protocol:
  - Use Q&A to ask questions you want to be SURE I see
  - Use chat (send to all, not just "send to panelists") for the game of Twitch Plays CS161
    - And press F (or really, just do anything in chat) for attendance tracking.
    - And if the chat annoys you, just scroll it off screen

### Internet of Shit...

Computer Science 161 Fall 2020

- A device produced by the lowest bidder...
  - That you then connect through the network
- This has a very wide attack surface
  - Methods where an attacker might access a vulnerability
- And its often incredibly cost sensitive
  - Very little support after purchase
    - So things don't get patched
  - No way for the user to tell what is "secure" or "not"
    - But they can tell what is cheaper!
    - And often it is *insanely* insecure:
       Default passwords on telnet of admin/admin...
       Trivial buffer overflows

## Net Of A Million Spies...

Computer Science 161 Fall 202

- Device only communicates through a central service
  - Greatly reduces the attack surface but...
- Most of the companies running the service are "Data Asset" companies
  - Make their money from advertising, not the product themselves
    - May actually subsidize the product considerably
  - Some you know about: Google, Amazon
  - Some you may not: Salesforce
- Only exception of note is Apple:
  - I may talk about HomeKit later...
     But you still have to trust that the HomeKit product doesn't report to a third party.

### A Tale from the Before Times

**Computer Science 161 Fall 2020** 

- I (used) to fly a fair amount
  - Conferences, panels, meetings, etc...

#### **Traveler Information**

#### Traveler 1 - Adults (age 18 to 64)

To comply with the TSA Secure Flight program, the traveler information listed here must exactly match the information on the government-issued photo ID that the traveler presents at the airport.

#### IE's Role in the Google-China War

By Richard Adhikari TechNewsWorld 01/15/10 12:25 PM PT

**Computer Science 161 Fall 2020** 

The hack attack on Google that set off the company's ongoing standoff with China appears to have come through a zero-day flaw in Microsoft's Internet Explorer browser. Microsoft has released a security advisory, and

researchers are hard at work studying the exploit. The attack appears to consist of several files, each a different piece of malware.

Computer security companies are scurrying to cope with the fallout from the Internet Explorer (IE) flaw that led to cyberattacks on Google (Nasdaq: GOOG) and its corporate and individual customers.

The zero-day attack that exploited IE is part of a lethal cocktail of malware that is keeping researchers very busy.

"We're discovering things on an up-to-the-minute basis, and we've seen about a dozen files dropped on infected PCs so far," Dmitri Alperovitch, vice president of research at McAfee Labs, told TechNewsWorld.

The attacks on Google, which appeared to originate in China, have sparked a feud between the Internet giant and the nation's government over censorship, and it could result in Google pulling away from its business dealings in the country.

#### Pointing to the Flaw

The vulnerability in IE is an invalid pointer reference, Microsoft (Nasdaq: MSFT) said in security advisory 979352, which it issued on Thursday. Under certain conditions, the invalid pointer can be accessed after an object is deleted, the advisory states. In special crafted attacks, like the ones launched against Coogle and its customers, IE can allow remote execution of code when the flaw is exploited.

## Disclaimer: x86-32

Computer Science 161 Fall 202

- For this class, we are going to use 32b x86...
  - Why?
- It is both common and weak...
  - Almost everyone in this class has access to an x86 system:
     Mac, Linux, Windows...
     And can run a 32b x86 virtual machine
  - 64b x86 systems generally include a lot better "mitigations":
     System defenses designed to limit exploitation in this manner
- But these attacks do apply to other microarchitectures
  - Phones are 64b ARM: Can still be exploited in this manner
  - The Internet of Things is mostly 32b or 64b ARM... and often neglects to include the mitigations!

### x86 vs RISC-V

#### Computer Science 161 Fall 2020

Moovo

- All RISC architectures are the same except for one or two 'seems like a good idea at the time' design decisions
   ... But x86 is a very different beast from a programing viewpoint
- RISC-V: 32 general purpose registers (well, 31 + x0...)
  - All operations are on data in registers apart from loads & stores
- x86: only a few registers
  - Operations can be directly on data in memory, including a large number relative to the stack
  - EG, add takes two operands, adds them together, and stores the result in the first
    - The first can be a register or memory location
    - The second can be a register, a memory location, or an immediate...
      - But the first and second can't both be a memory location?!?

## The main x86 registers...

Computer Science 161 Fall 2020

- General purpose: EAX-EDX
  - What you use for computing and other stuff, sorta...
- Indexes & Pointers
  - EBP: "Frame pointer": points to the top/start of the current call frame on the stack
  - ESP: "Stack pointer": points to the current stack (Remember, stack grows down!)
    - PUSH and POP
      - Decrement the stack pointer and store something there
      - Load something and increment the stack pointer
    - Most operations are done with data on the stack…

## Linux (32-bit) process memory layout

**Computer Science 161 Fall 2020** OXFFFFFFF **Reserved for Kernel** -0xC000000 user stack \$esp shared\_\_braries  $-0 \times 40000000$ brk run time heap static data segment text segment (program) Loaded from exec  $-0 \times 08048000$ 

unused

 $-0 \times 0 0 0 0 0 0 0$ 

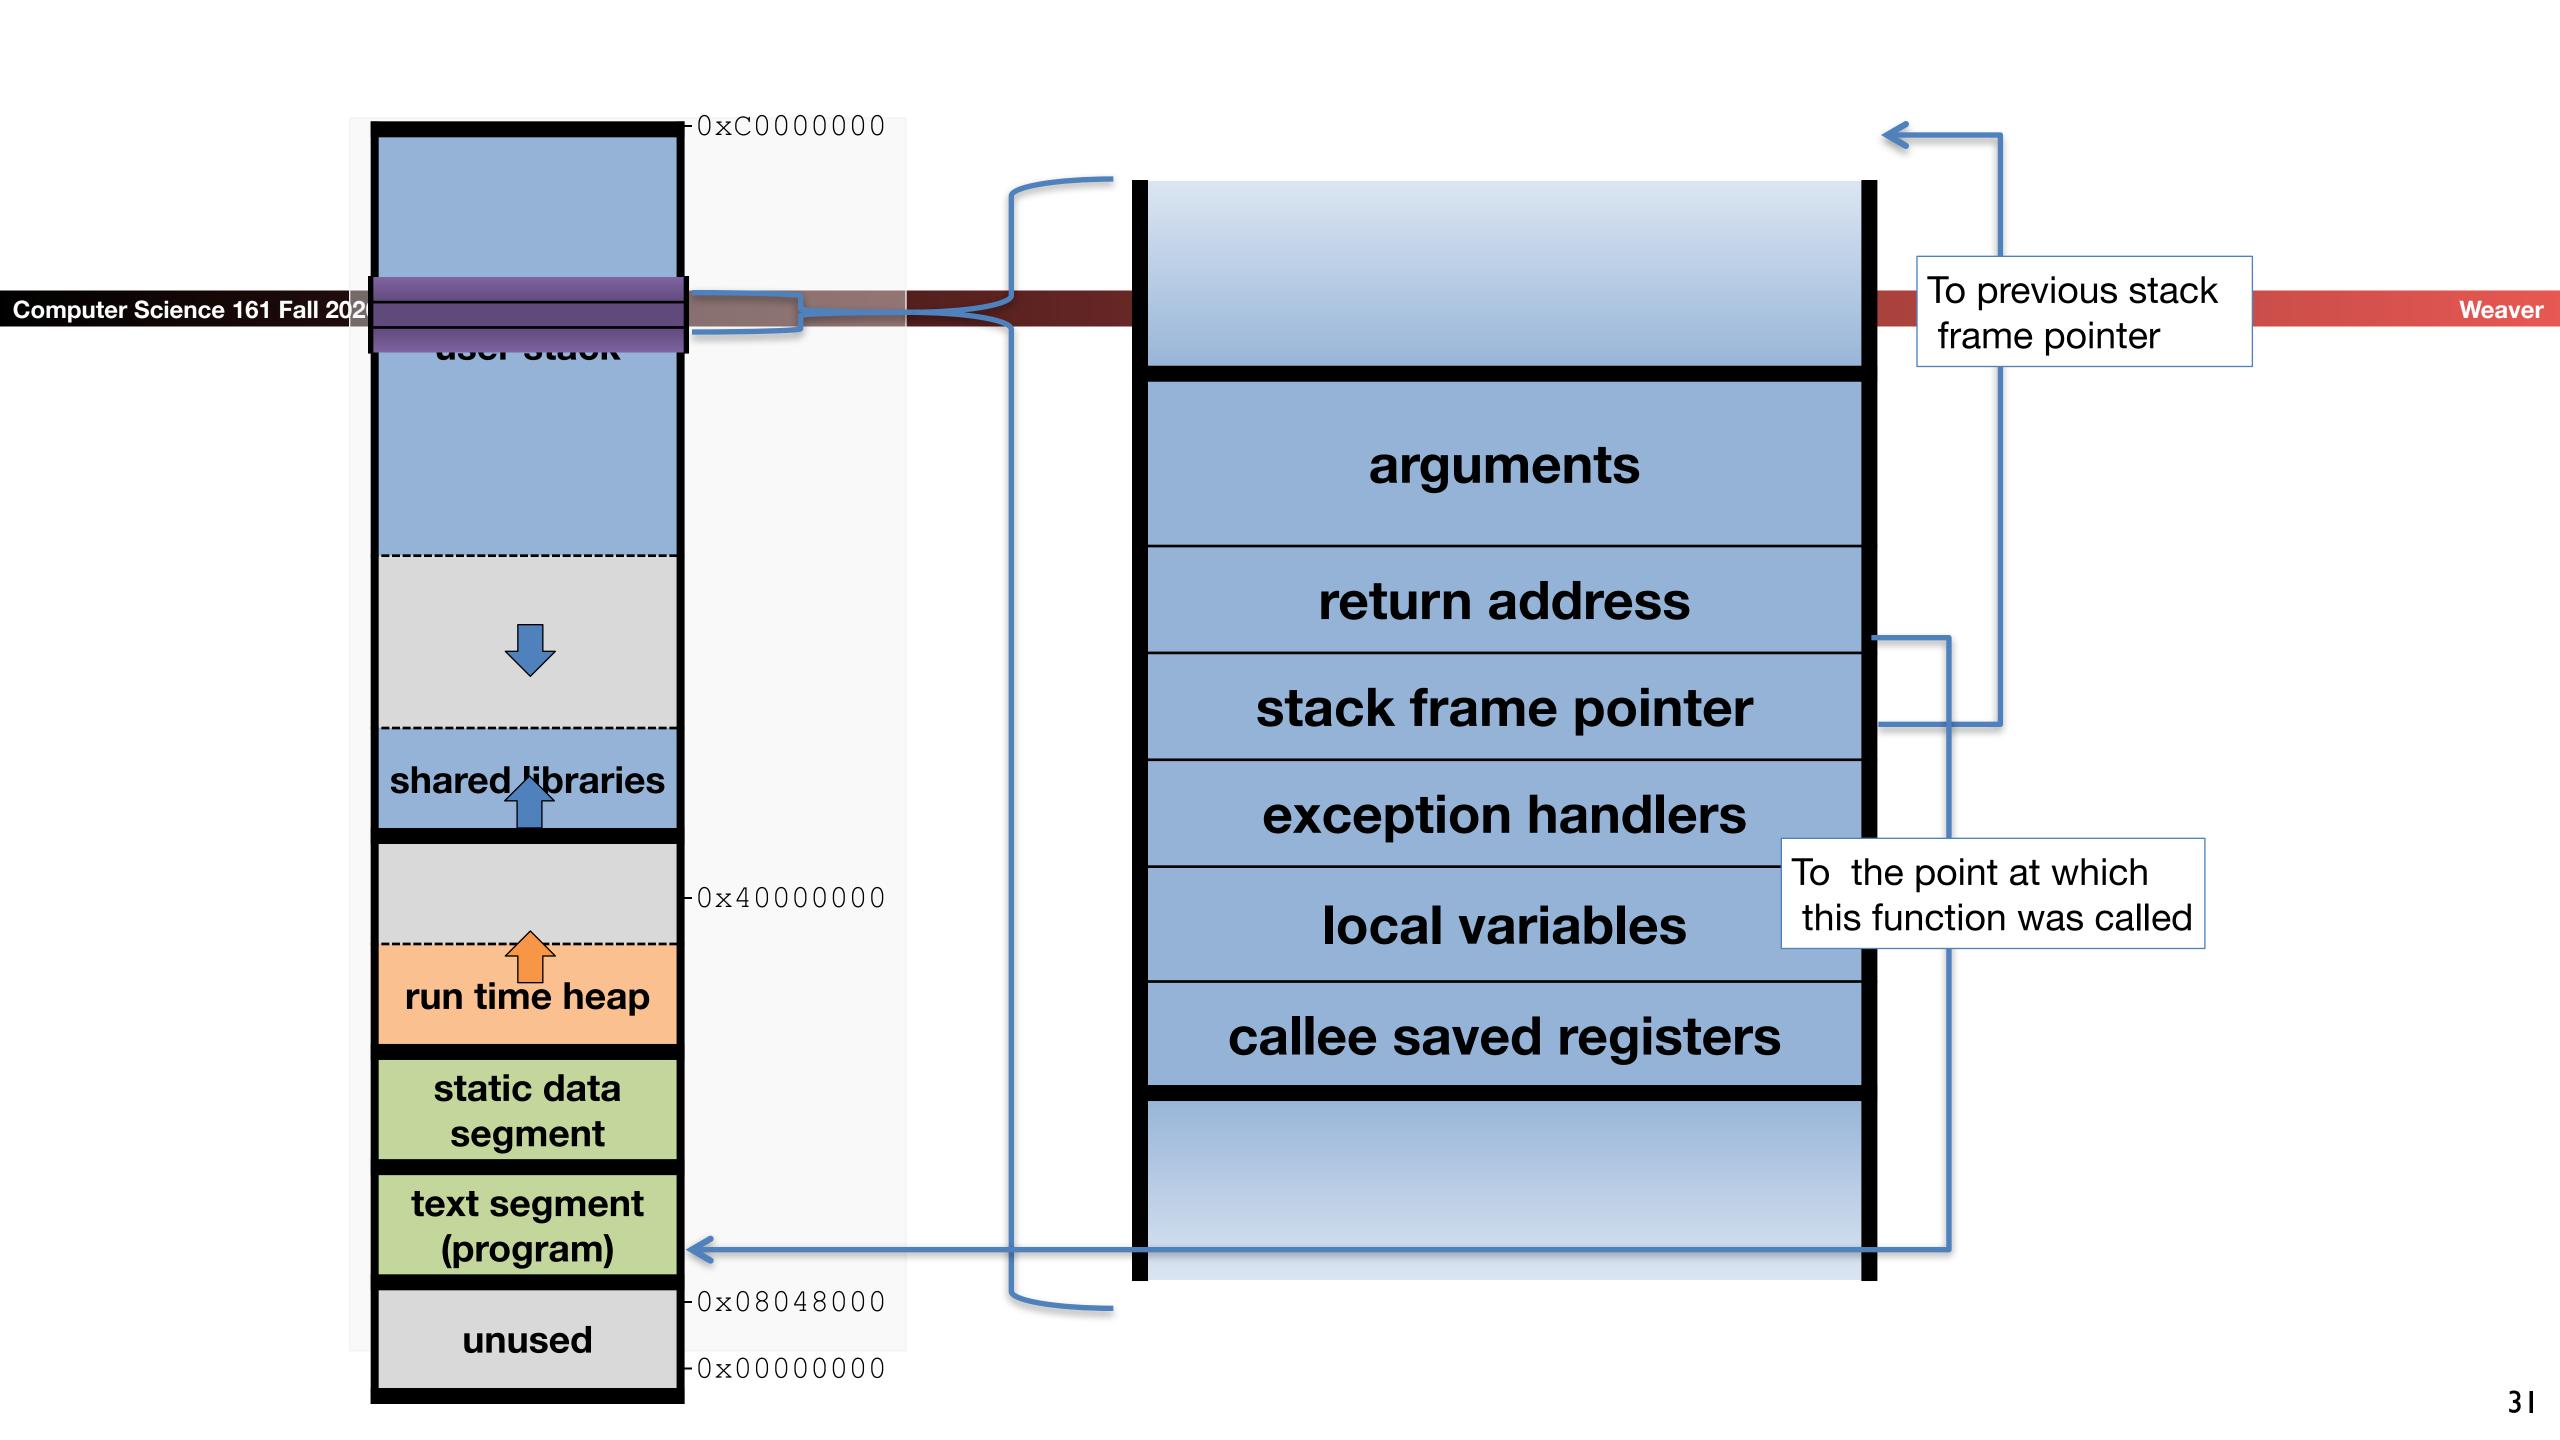

Weaver

29

## x86 function calling

Computer Science 161 Fall 202

- Place the arguments on the stack
  - Compare with RISC-V where the first arguments are in registers
- CALL the function
  - Which pushes the return address onto the stack (RIP == Return Instruction Pointer)
- do your stuff...
  - Start by saving the old EP on the stack (SFP == Saved Frame Pointer)
- Restore everything
  - Reload EBP, pop ESP as necessary
- RET
  - Which jumps to the return address that is currently pointed to by ESP
  - And can optionally pop the stack a lot further...

```
void safe() {
  char buf[64];
  ...
  fgets(buf, 64, stdin);
  ...
}
```

```
void safer() {
  char buf[64];
  ...
  fgets(buf, sizeof(buf), stdin);
  ...
}
```

```
void vulnerable(int len, char *data) {
  char buf[64];
  if (len > 64)
    return;
  memcpy(buf, data, len);
}
```

```
memcpy(void *s1, const void *s2, (size_t) n);
```

size\_t is *unsigned*:
What happens if len == -1?

```
void safe(size_t len, char *data) {
  char buf[64];
  if (len > 64)
    return;
  memcpy(buf, data, len);
}
```

Weaver

```
void f(size_t len, char *data) {
  char *buf = malloc(len+2);
  if (buf == NULL) return;
  memcpy(buf, data, len);
  buf[len] = '\n';
  buf[len+1] = '\0';
}
```

Is it safe? Spam the Chat!

```
Vulnerable!

If len = 0xffffffff, allocates only 1 byte
```

#### **Broward Vote-Counting Blunder Changes Amendment Result**

Computer Science 161 Fall POSTED: 1:34 pm EST November 4, 2004

**BROWARD COUNTY, Fla. --** The Broward County Elections Department has egg on its face today after a computer glitch misreported a key amendment race, according to WPLG-TV in Miami.

Amendment 4, which would allow Miami-Dade and Broward counties to hold a future election to decide if slot machines should be allowed at racetracks, was thought to be tied. But now that a computer glitch for machines counting absentee ballots has been exposed, it turns out the amendment passed.

The software is not geared to count more than 32,000 votes in a precinct. So what happens when it gets to 32,000 is the software starts counting backward," said Broward County Mayor Ilene Lieberman.

That means that Amendment 4 passed in Broward County by more than 240,000 votes rather than the 166,000-vote margin reported Wednesday night. That increase changes the overall statewide results in what had been a neck-and-neck race, one for which recounts had been going on today. But with news of Broward's error, it's clear amendment 4 passed.

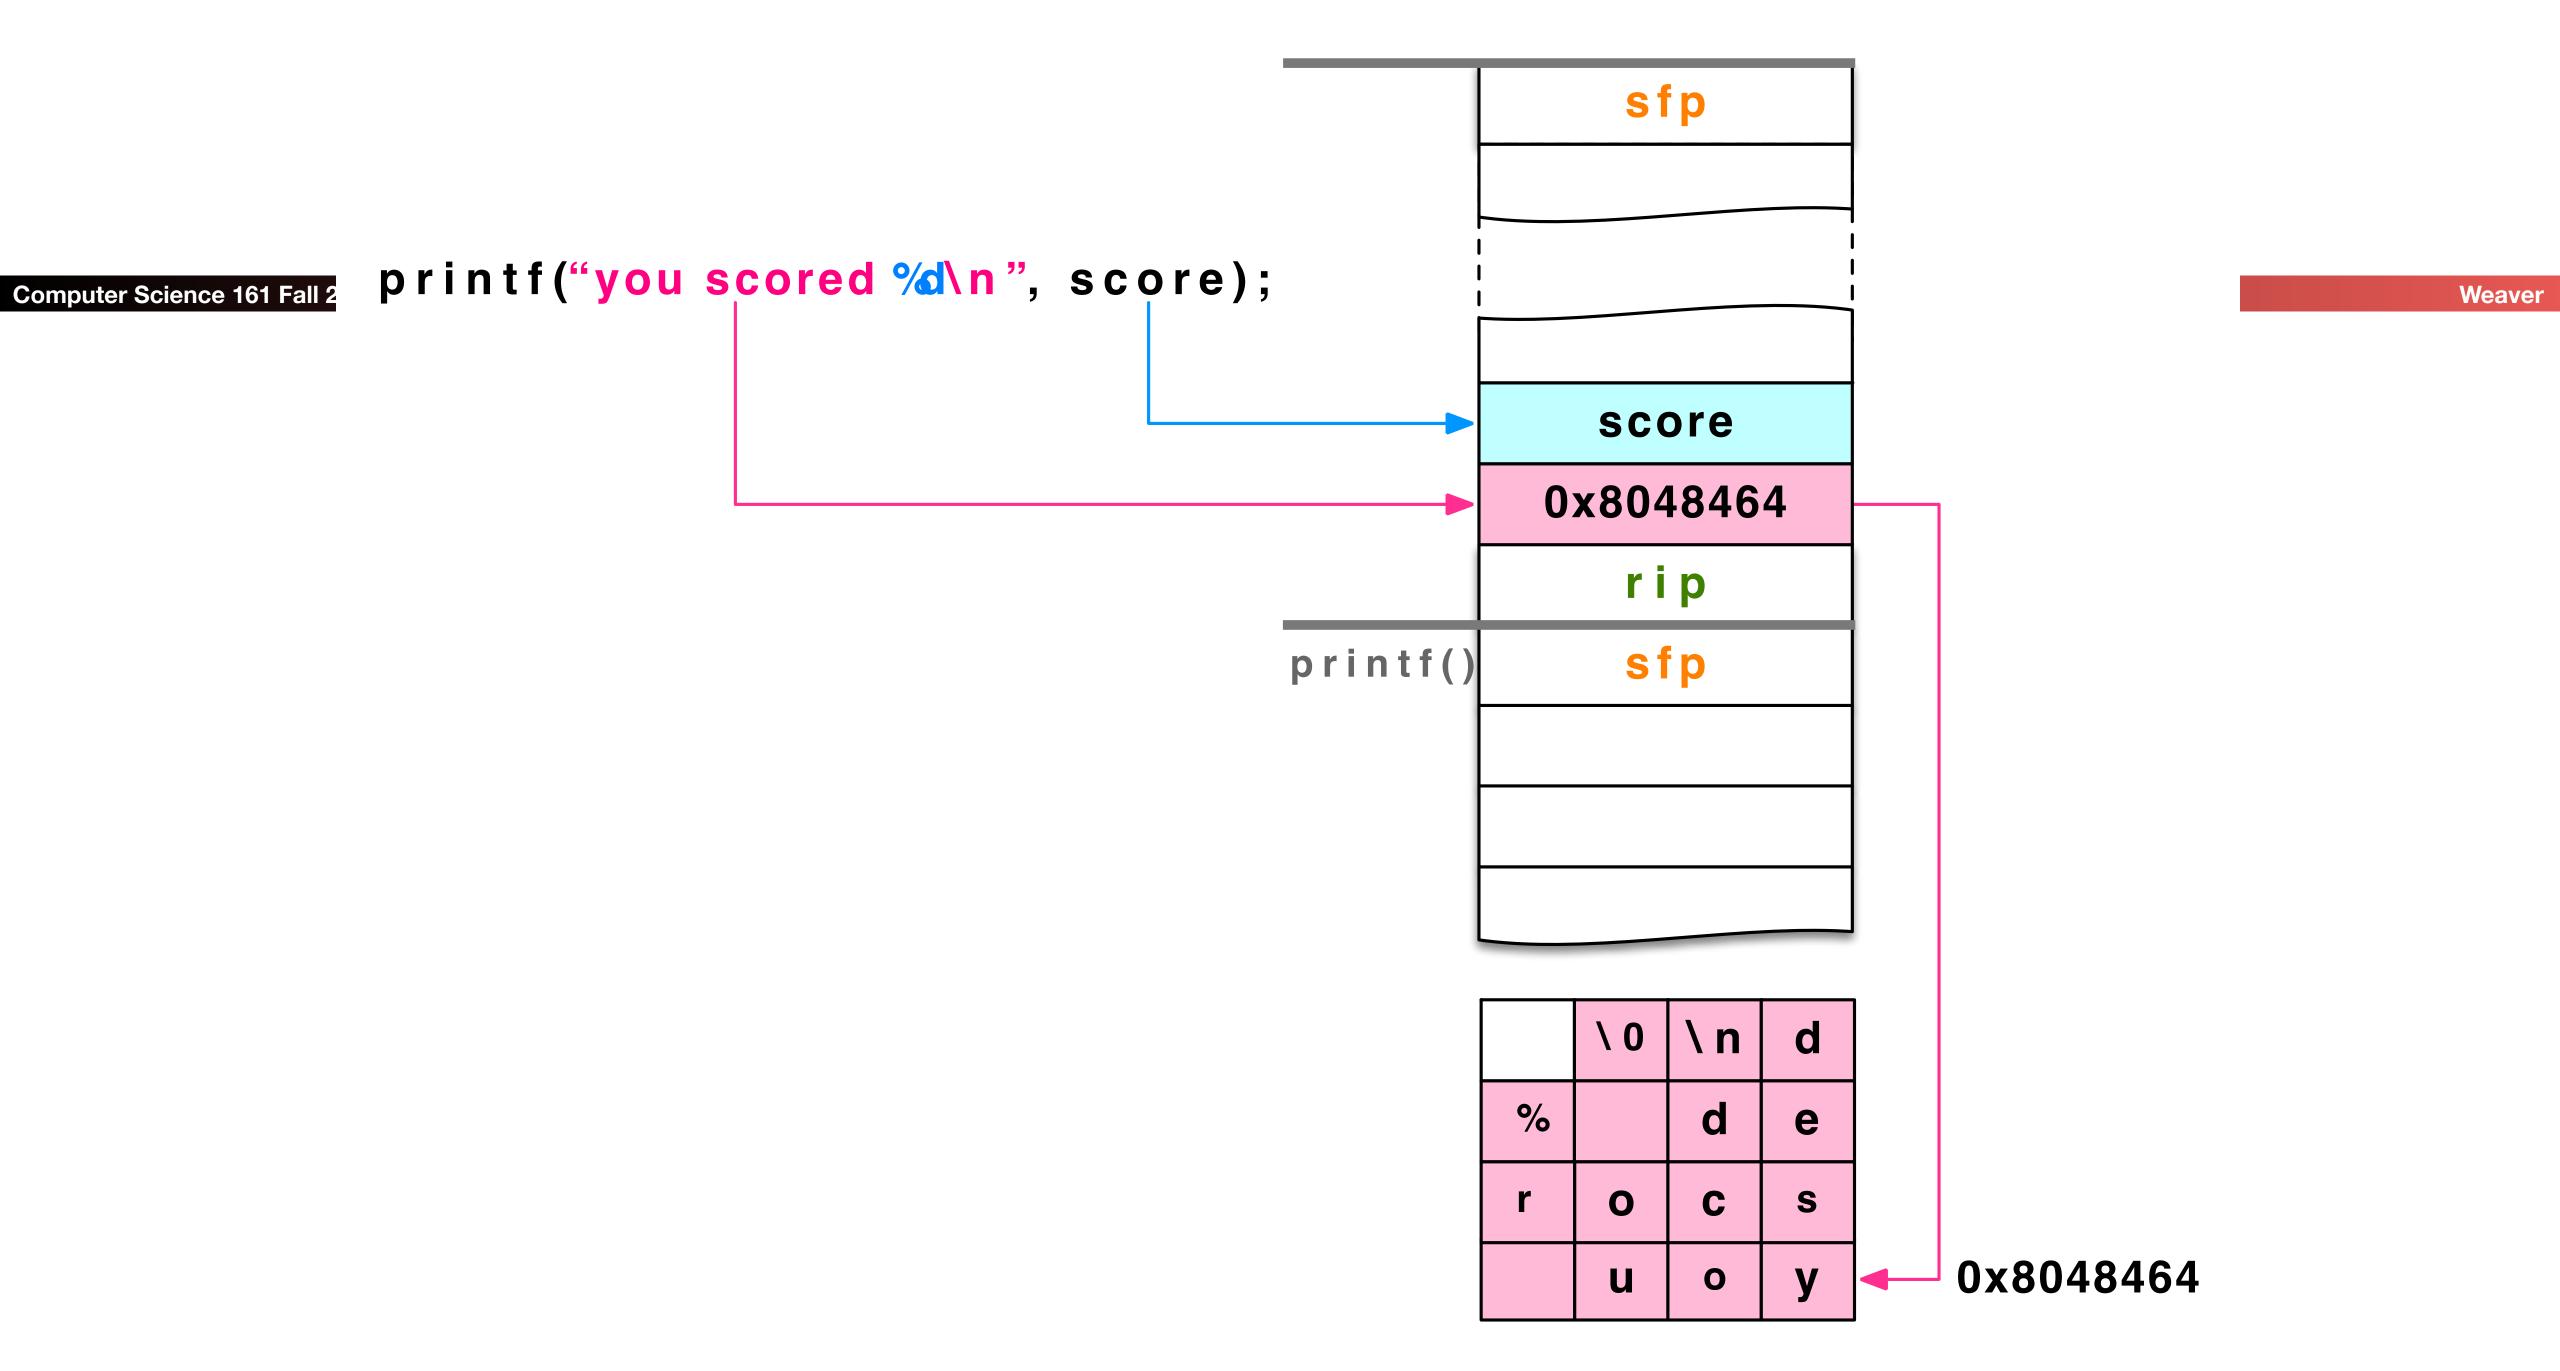

**Broward County Mayor** Ilene Lieberman says voting counting error is an "embarrassing mistake."

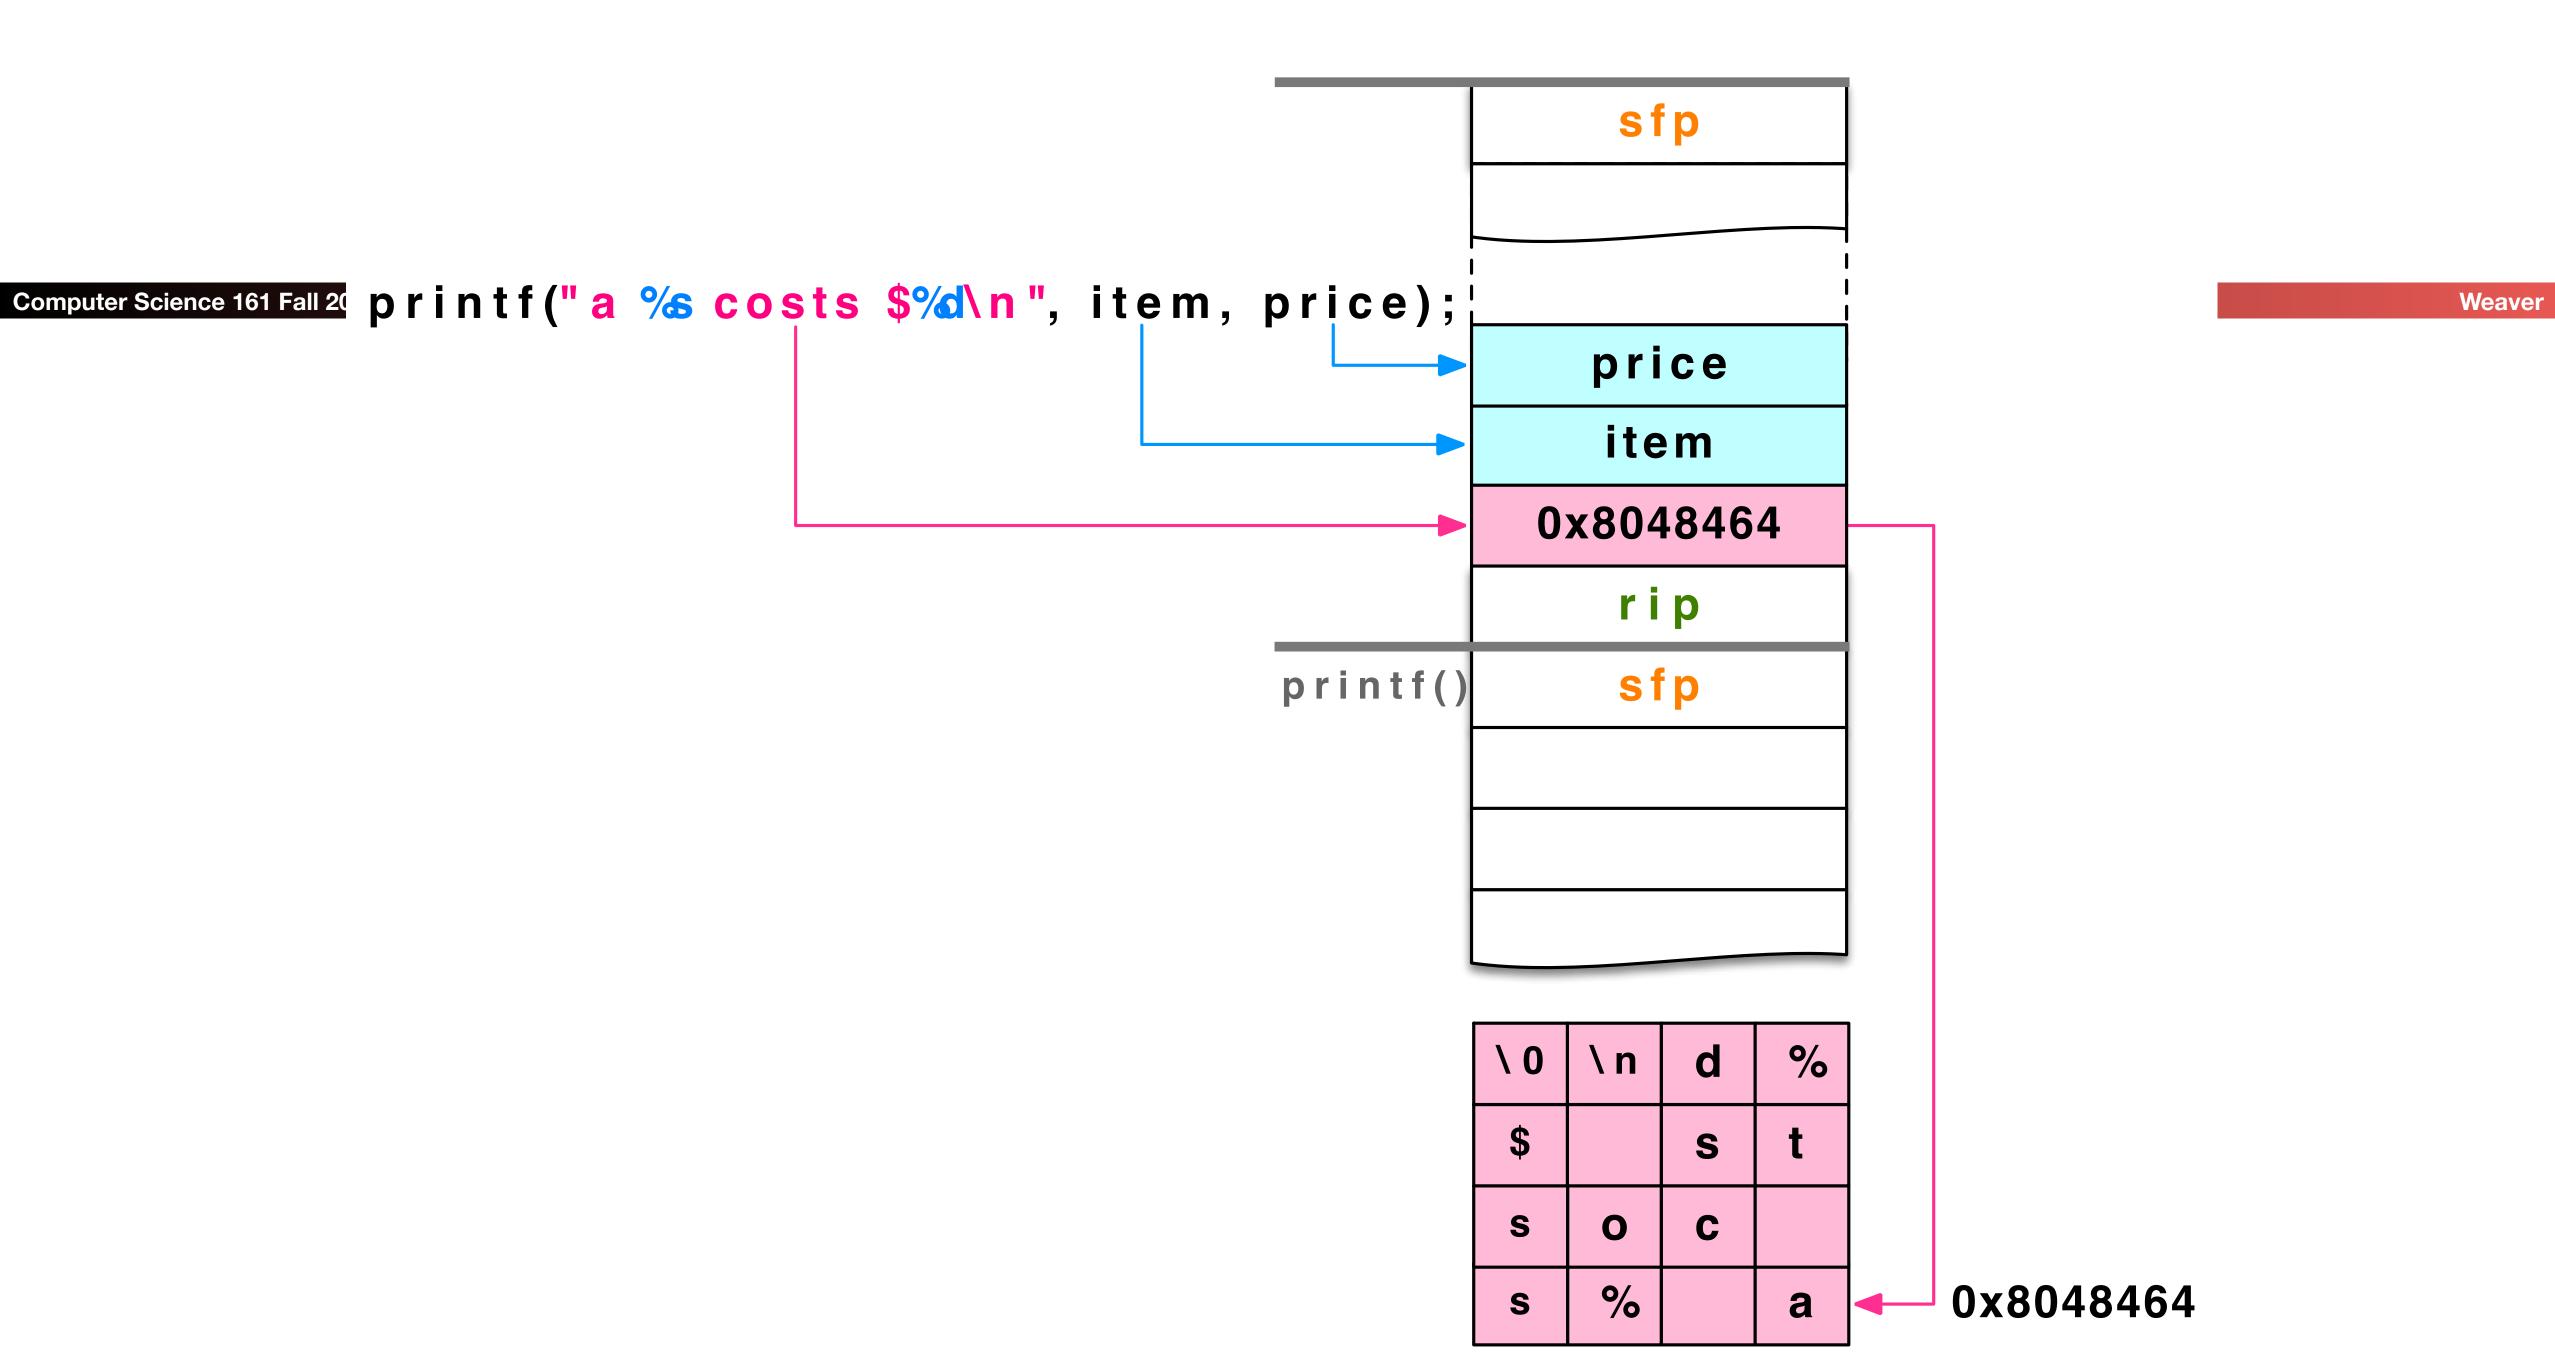

**Computer Science 161 Fall 2020** 

```
void vulnerable() {
  char buf[64];
  if (fgets(buf, 64, stdin) == NULL)
    return;
  printf(buf);
}
```

```
printf("you scored %d\n", score);
```

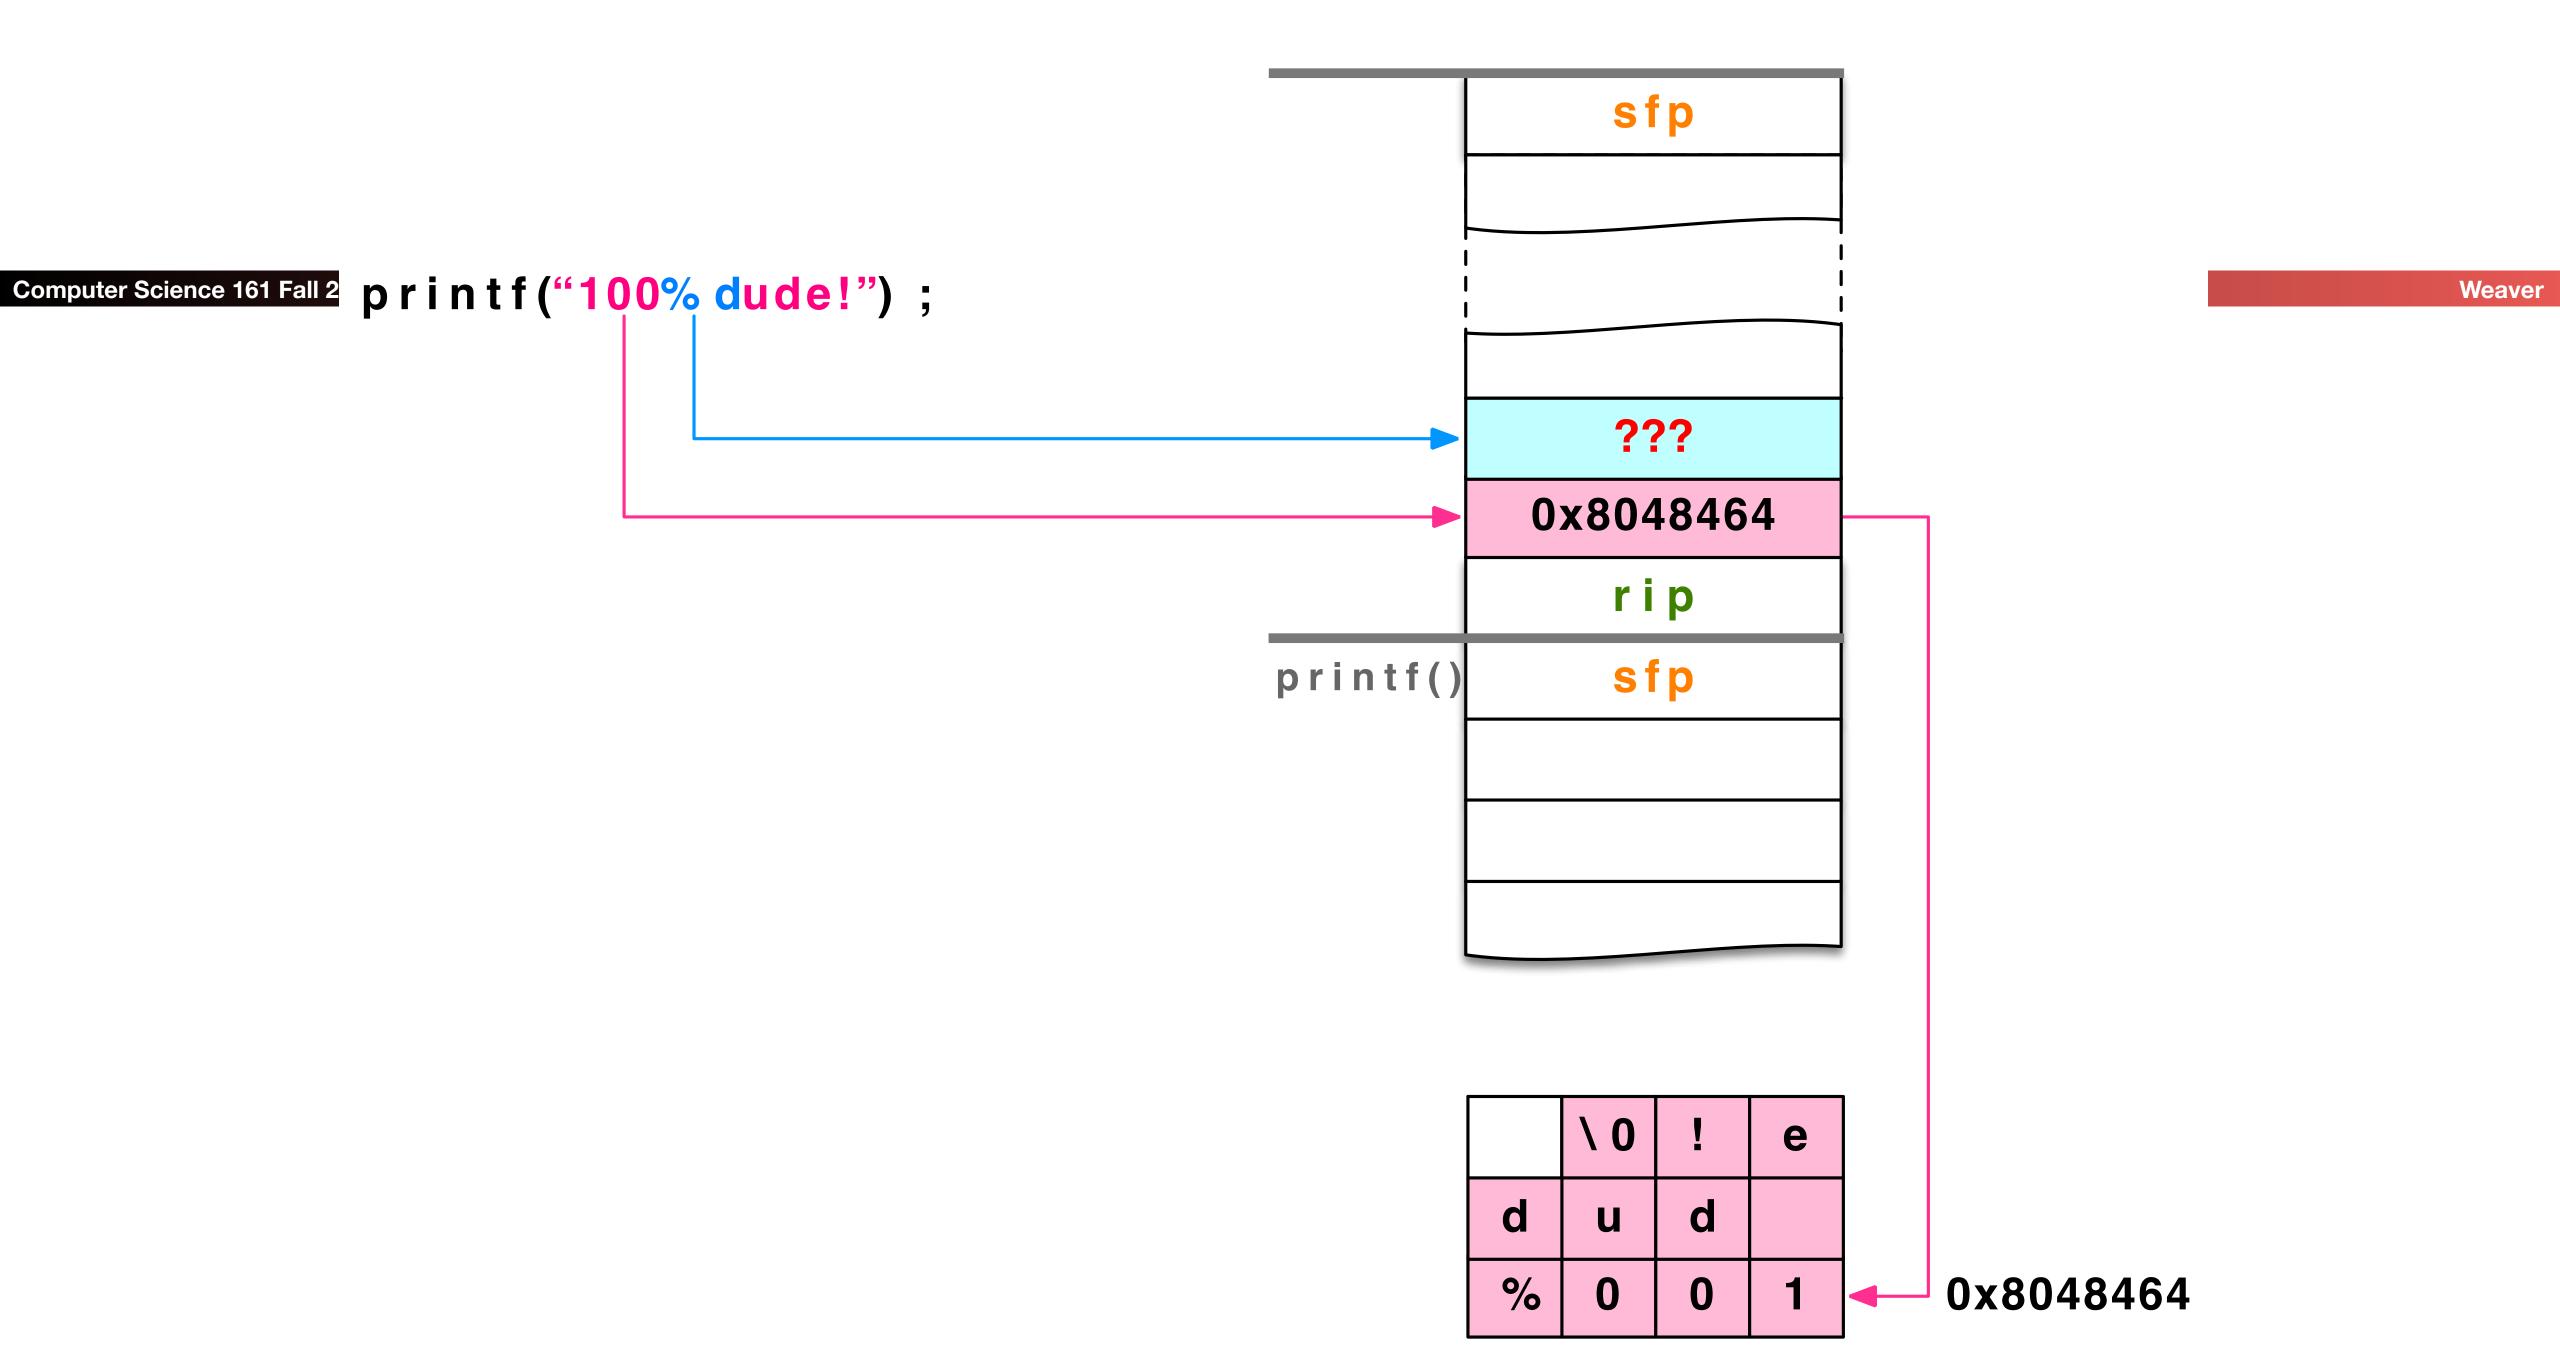

printf("a %s costs \$%d\n", item, price);

### Fun With printf format strings...

**Computer Science 161 Fall 2020** 

```
printf("100% dud Format argument is missing!
```

### More Fun With printf format strings...

Computer Science 161 Fall 2020

```
printf("100% dude!");
     ⇒ prints value 4 bytes above retaddr as integer
printf("100% sir!");
     ⇒ prints bytes pointed to by that stack entry
        up through first NUL
printf("%d %d %d %d ...");
     ⇒ prints series of stack entries as integers
printf("%d %s");
     ⇒ prints value 4 bytes above retaddr plus bytes
         pointed to by preceding stack entry
printf("100% nuke'm!");
```

%n writes the number of characters printed so far into the corresponding format argument.

```
int report cost(int item num, int price) {
  int colon offset;
  printf("item %d:%n $%d\n", item num,
                  &colon offset, price);
  return colon offset;
report cost(3, 22) prints "item 3: $22"
     and returns the value 7
report cost(987, 5) prints "item 987: $5"
     and returns the value 9
```

### Fun With printf format strings...

Computer Science 161 Fall 2020 printf("100% dude!"); ⇒ prints value 4 bytes above retaddr as integer printf("100% sir!"); ⇒ prints bytes pointed to by that stack entry up through first NUL printf("%d %d %d %d ..."); ⇒ prints series of stack entries as integers printf("%d %s"); ⇒ prints value 4 bytes above retaddr plus bytes pointed to by preceding stack entry printf("100% nuke'm!"); ⇒ writes the value 3 to the address pointed to by stack entry

**Computer Science 161 Fall 2020** 

```
void safe() {
  char buf[64];
  if (fgets(buf, 64, stdin) == NULL)
    return;
  printf("%s", buf);
}
```

### It isn't just the stack...

Computer Science 161 Fall 202

Weeve

- Control flow attacks require that the attacker overwrite a piece of memory that contains a pointer for future code execution
  - The return address on the stack is just the easiest target
- You can cause plenty of mayhem overwriting memory in the heap...
  - And it is made easier when targeting C++
- Allows alternate ways to hijack control flow of the program

## Compiler Operation: Compiling Object Oriented Code

**Computer Science 161 Fall 2020** 

Weaver

```
class Foo {
                                                    vtable ptr (class Foo)
   int i, j, k;
   public virtual void bar() { ... }
   public virtual void baz() { ... }
                                                            k
                                                      ptr to Foo::bar
                                                      ptr to Foo::baz
```

• • •

# So Targets For Overwriting...

**Computer Science 161 Fall 2020** 

- If you can overwrite a vtable pointer...
  - It is effectively the same as overwriting the return address pointer on the stack:
     When the function gets invoked the control flow is hijacked to point to the attacker's code
    - The only difference is that instead of overwriting with a pointer you overwrite it with a pointer to a table of pointers...
- Heap Overflow:
  - A buffer in the heap is not checked:
     Attacker writes beyond and overwrites the vtable pointer of the next object in memory
- Use-after-free:
  - An object is deallocated too early:
     Attacker writes new data in a newly reallocated block that overwrites the vtable pointer
  - Object is then invoked

### Magic Numbers & Exploitation...

Computer Science 161 Fall 20

Exploits can often be very brittle

- You see this on your Project 1: Your ./egg will not work on someone else's VM because the memory layout is different
- Making an exploit robust is an art unto itself: e.g. EXTRABACON...
- EXTRABACON is an NSA exploit for Cisco ASA "Adaptive Security Appliances"
  - It had an exploitable stack-overflow vulnerability in the SNMP read operation
  - But actual exploitation required two steps:
     Query for the particular version (with an SMTP read)
     Select the proper set of magic numbers for that version

### A hack that helps: NOOP sled...

Computer Science 161 Fall 202

Woovo

- Don't just overwrite the pointer and then provide the code you want to execute...
- Instead, write a large number of NOOP operations
  - Instructions that do nothing
- Now if you are a little off, it doesn't matter
  - Since if you are close enough, control flow will land in the sled and start running...

#### ETERNALBLUE is another NSA exploit

- Stolen by the same group ("ShadowBrokers") which stole EXTRABACON
- Eventually it was very robust...
  - This was "god mode": remote exploit Windows through SMBv1 (Windows File sharing)
- But initially it was jokingly called ETERNALBLUESCREEN
  - Because it would crash Windows computers more reliably than exploitation.

Plugin Category: Special

Current and former officials defended the agency's handling of EternalBlue, saying that the NSA must use such volatile tools to fulfill its mission of gathering foreign intelligence. In the case of EternalBlue, the intelligence haul was "unreal," said one

The NSA also made upgrades to EternalBlue to address its penchant for crashing targeted computers — a problem that earned it the nickname "EternalBlueScreen" in reference to the eerie blue screen often displayed by computers in distress.

### And Now A More Detailed Example...

**Computer Science 161 Fall 2020** 

- Walking through a function call in detail...
  - Slides from Matthias Vallentin
